### Overview

Solution: Ensure that the distribution box is reliably grounded, and the grounding wire should have sufficient cross-sectional area and be connected to the grounding network. Regular maintenance inspections are the key to ensuring the long-term safe operation of cable. Today, we're diving deep into the world of distribution box grounding, breaking down the standards, and shining a light on those sneaky mistakes that even experienced electricians sometimes make. Each DISTRIBUTION BOX and controller must be grounded. 26 mm<sup>2</sup> (10 AWG) ground wire must be used, and in all other markets a 6 mm<sup>2</sup> must be used. These high levels typically require line tripping to remove the fault from the system. • Good system grounding provides the path for normal load and fault currents while maintaining load and controls temporary overvoltage. Good equipment grounding ensures personnel safety. Most North American distribution systems have a neutral that acts as a return conductor and as an equipment. Repeated grounding means that in a system where the neutral point is directly grounded, a metal wire is used to connect the grounding device at one or more places on the neutral main line. In the low-voltage three-phase four-wire neutral point directly grounded line, the construction unit should. There are several factors that make substation grounding absolutely necessary.
