

How optical modules achieve different wavelengths

Overview

The optics module has two types: a type that splits light rays at a specific ratio, and a dichroic type that reflects only light of a specific wavelength band. It achieves the best transmission effect when the optical module matches the center wavelength of the optical signal it transmits. Moreover, each wavelength carries an independent data stream. Therefore, network operators expand capacity. Modern optical networks use a variety of modulation schemes in order to transport the data across hundreds to thousands of kilometers. Wavelength or frequency - each channel in a DWDM network uses a. A CWDM SFP module is an optical transceiver that uses Coarse Wavelength Division Multiplexing (CWDM) technology to transmit multiple data channels over a single strand of single-mode fiber, helping networks expand capacity without deploying additional fiber.
