

Principle of Single-Mode Fiber Optic Temperature Measurement and Alarm System

Overview

The fiber optic temperature sensor working principle is based on a well-characterized physical phenomenon: the temperature-dependent fluorescence decay of a rare-earth phosphor material. The all-dielectric, non-conductive measurement path provides complete electromagnetic immunity, galvanic isolation beyond 100 kV, and intrinsically safe operation — capabilities. Our company has independently developed the DTS-BLY-5S (SMV), which features low power consumption of as low as 6W, a three-proof motherboard (anti-fungus, moisture-proof, and salt spray-proof), a temperature sensing distance of over 24 km, a maximum of 16 channels, compatibility with fiber cables. A fiber optic sensor generally guides light to and from a measurement zone where the light is modulated by the measurand of interest and returned along the same or a different optical fiber to a detector at which the optical signal is interpreted. Unlike traditional electrical temperature sensors (e., thermocouples, RTDs), fiber optic sensors offer significant advantages such as immunity to electromagnetic interference. This article explores the structure, working principles, advantages, and disadvantages of Fiber Optic Temperature Sensors.
